The zinc doped iron oxide nanoparticles were successfully synthesized by hydrothermal process at temperatures of 150 and 180°C for time of 6, 12, and 22 h. The average crystallite sizes of the nanoparticles were in the range of 14–24 nm with small size distribution. SEM analysis confirmed that all of $Zn_{0.25}Fe_{2.75}O_4$ nanoparticles show a spherical form. The reaction temperature rise up to 180°C led to the increasing of crystallinity of nanoparticles. All nanoparticles showed a superparamagnetic behaviour at room temperature.

Keywords: Nanoparticles, hydrothermal process, Zn doped iron oxide, XRD, magnetic properties.

Introduction

Zinc is one of the commonly used metal dopants into iron oxide due to minimal toxicity. In literature, various synthesis methods have been proposed for producing Zn doped iron oxide and zinc ferrite nanoparticles, such as co-precipitation method, hydrothermal, sol-gel method, thermal decomposition and so on 1-10. The hydrothermal process is simple and inexpensive in which non-harmful materials are used. The particle size and the magnetic property of nanoparticles can be controlled by arranging the reaction temperature and time, and the other parameters⁸. The goal of this work is to analyze effects of reaction temperature and reaction time on the structural and magnetic properties of the synthesized Zn_{0.25}Fe_{2.75}O₄ nanoparticles by using hydrothermal method.

Synthesis of Zn_{0.25}Fe_{2.75}O₄ nanoparticles

The synthesis of sample has been performed by a hydrothermal route. In a typical experimental procedure, 4 mmol FeCl₃.6H₂O, 1.5 mmol FeCl₂.4H₂O, 0.5 mmol ZnCl₂ solutions were dissolved in 40 ml distilled water then into the two necked round bottom flask. The mixture was stirred at 500 rpm for 2 min under nitrogen gas. After that 5 ml of NH₄OH were dropped to the solution. Then the solution was transferred into the Teflon-sealed autoclave for different temperature and different reaction time, as shown in Table 1. The black precipitates were washed with distilled water in two

times and the recent precipitates were dried at 60°C.

Table 1. The hydrothermal conditions used to synthesize

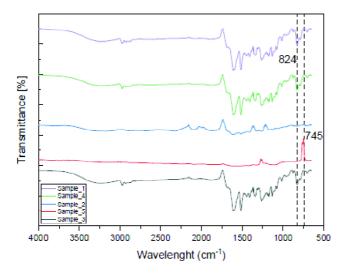

Zn _{0.25} Fe _{2.75} O ₄ nanoparticles				
Sample	Reaction temperature	Reaction time		
No.	(°C)	(h)		
Sample_1	150	6		
Sample_2	150	12		
Sample_3	150	22		
Sample_4	180	6		
Sample_5	180	12		

Structural and phase analysis results

To record the structural features of nanoparticles, infrared spectrum measurements were taken using Perkin-Elmer Fourier transform infrared spectroscopy between 4000 and 500 cm⁻¹. FTIR spectra of nanoparticles were given in Fig. 1. As seen from the spectrum, in the region of 745–830 cm⁻¹, the characteristic Fe-O magnetite bending (Fe³⁺-O bound) were observed.

To investigate crystal structure of the nanoparticles were analyzed by using Rigaku X-ray diffractometer, with CuK radiation (λ = 0.154 nm). In Fig. 2 showed that the XRD patterns of samples synthesized at different hydrothermal

Caliskan et al.: The effect of reaction temperature and times on structural and magnetic properties of Zn_{0.25}Fe_{2.75}O₄

conditions, respectively. All nanoparticles have the same characteristic (220), (311), (400), (422), (511) and (400) peaks of cubic spinel structure with cell constant $a=8.4\pm0.01$ Å, which is good agreement with the value in the literature (JCPDS cad no. 89-1012, with a=8.433 Å)¹¹. There is no obvious impurity peak can be detected. In Fig. 2, to observe the effect of the reaction temperatures applied on the synthesized nanoparticles structure, the reaction time was kept approximately the same in Sample_2 and Sample_5 samples. It can be seen that the peak intensities decreased while the wideness of the peaks decreased as the reaction temperature increased with the same reaction time.

The average crystal size D (nm), of the $\rm Zn_{0.25}Fe_{2.75}O_4$ nanoparticles were calculated from the highest intensity peak (311) using the Debye-Scherrer equation⁵ and the presented in Table 2. The D (nm) of nanoparticles synthesized at 150°C and 180°C for 12 h were calculated to be 21 and 24 nm, respectively. The increase of the reaction temperature the nanoparticle size increased.

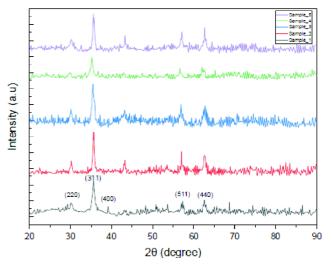

Fig. 2. XRD patterns of Zn_{0.25}Fe_{2.75}O₄ nanoparticles.

To analyze the effect of the reaction time on the nanoparticle size, as the reaction time was increased from 6 to 22 h at 150°C, the D (nm) increased from 14 to 20 nm, respectively. To get more detail of the investigation, at 180°C, the D (nm) of the nanoparticles synthesized for 3 and 12 h were found to be 23 and 25 nm, respectively. The D (nm) increased with increasing reaction time.

Using XRD data, the lattice parameter (α) , crystal size (D), X-ray density (ρ) , dislocation density (δ) , and special surface area (S) of the samples were calculated using the following equations¹². The results are presented in Table 2.

Since the crystal lattice parameter of magnetite is compatible with the literature for all three samples, the crystal structure of Fe_3O_4 is formed. When the structure is determined from the XRD pattern, we can also calculate the volume and mass of the cell, so that we can find the density of the sample.

The dislocation density (δ), defined as the length of the dislocation lines per unit volume of crystal¹³, Sample 1 is 2

Table 2. Values of the D , α , ρ , δ and S of the samples					
Sample	D	α	ρ	δ	S
No.	(nm)	(nm)	(g/cm ³)	$(10^{15}\mathrm{m}^{-2})$	$(10^4 \text{m}^2/\text{g})$
Sample_1	14.3	0.84	6.80	4.9	6.17
Sample_2	21.1	0.83	6.96	2.24	4.08
Sample_3	22	0.84	6.76	2.01	4.03
Sample_4	23	0.84	6.84	1.8	3.98
Sample_5	24	0.85	6.9	1.78	3.74

times higher than other samples. The surface area (S) is changed with reaction time and temperature.

The surface morphology of the nanoparticles was analyzed by scanning electron microscopy (SEM) using JEOL electron microscope 6700 coupled with EDX spectroscopy. SEM results show that all synthesized nanoparticles show a spherical shape. When reaction temperature was increased from 150° to 180°C, the crystallinity of nanoparticles increased. SEM microscopies of some samples are demonstrated in Fig. 3, respectively. The particle size increases with increasing reaction time and the surface morphology of the nanoparticles remains without change.

The EDX spectrum of $Zn_{0.25}Fe_{2.75}O_4$ samples for differ-

ent reaction temperature and time are shown in Fig. 4. As can be seen, the spectrum confirms the presence of zinc dopant in Fe_3O_4 . The spectrum recorded peak of the particles which show Zn, Fe and O related peaks. EDX analysis gives information about how much amount of Zn atom has really entered into the magnetite nanoparticles¹⁴.

When reaction temperatures and times increased from 150°C to 180°C and 3 h to 22 h; only 5.63% to 9.18% of Zn atoms have entered into magnetite. The first condition of the sample, it is seen that only 5.63% of Zn atoms entered into the structure and remaining Zn atoms could have been washed away¹⁴. Weight percentage (wt%) values of atoms are shown in Table 3. Elemental analys is approves that Zn

Table 3. Values of elemental analysis of Zn _{0.25} Fe _{2.75} O ₄					
1 4.0.0		anoparticles	0.25. 02.75	-4	
Sample		Composition (wt%) Elements			
No.	Zn	Fe	0	Total	
Sample_1	5.63	73.78	20.59	100	
Sample_2	5.81	83.41	10.78	100	
Sample_3	7.31	79.52	13.17	100	
Sample_4	7.35	79.81	12.84	100	
Sample_5	9.18	73.5	17.32	100	

element entered in the structures. EDX analysis approved that the nanoparticles are consisted of Zn, Fe, and O element. There is no other impurity.

To determine the magnetic behavior of the samples, ESR analysis was first performed with Bruker EMX X-band spectrometer and the Jeol Brand-JES-FA300 ESR spectrometer¹⁵. The ESR patterns for all five samples are shown in Fig. 5.

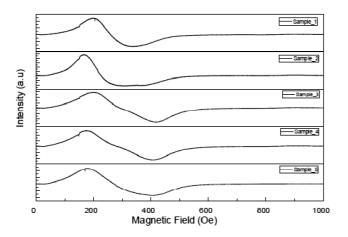

Fig. 5. ESR spectra of samples.

samples.

Relaxation times of the synthesized samples; T_2 , unpaired electron numbers; $N_{\rm s}$, signal intensities from peak to peak; $I_{\rm pp}$, full width half maximum; $\Delta H_{1/2}$, Lande factor; g and asymmetry factor; $P_{\rm asy}$ were calculated using the equations given below^{16–19}. All results of calculations are given in Table 4.

The resonance line width between two peaks is obtained from the FWHM value of the resonance spectrum.

The g value of the free electron is about 2. If the ratio of the magnetic moment to the angular moment of the system differs from that of the free electron, this difference comes from the spin-orbit match. Thus, the change in the value of g can also provide information about atomic or molecular orbitals containing unpaired electrons.

The resonance line width between two peaks is obtained from the FWHM value of the resonance spectrum. This width comes from the relaxation time of the excited electron. It was determined that when the crystal size increased, the T_2 value decreased.

Physical Properties Measurement System (PPMS) of Quantum Design Model 6000 device was used to get additional information about the magnetic properties of the synthesized $Zn_{0.25}Fe_{2.75}O_4$ structures.

All samples show super paramagnetic behavior, results are shown in Fig. 6. The sample of Sample_3 has the highest saturation value. The main reason of it was the reaction time should have been long for 150° C. Except for this sample, the highest saturation value was obtained when the reaction time was 12 h for 180° C which was named Sample_5. And the value was 89 emu/g. Besides, the highest remanent magnetization (M_r) value which is equal to 1 emu/g was ob-

Table 4. Values of g value, ΔH_{pp} , I_{pp} , N_s , T_2 , P_{asy} of the samples						
Sample No.	g-Value	$\Delta H_{\rm pp}$ (mt)	l _{pp}	N _s	$T_2 (10^{-11} \mathrm{s})$	P_{asy}
Sample_1	2.50	144.46	4416.4	244.8	1.80	2.4
Sample_2	2.87	135.137	3528.4	183.7	1.67	3.1
Sample_3	2.20	218.878	5558.0	758.8	1.36	2.0
Sample_4	2.27	235.02	6098.4	960	1.22	2.6
Sample_5	2.39	227.9	4990	738.6	1.21	2.3

It is seen that all samples have unpaired electrons and all samples exhibit magnetic behavior. The sample of Sample_5 appears to have a larger ESR peak that the other served in the Sample_5 sample. The lowest saturation magnetization value was observed in the sample of Sample_1 with the smallest particle size in this experimental calculation.

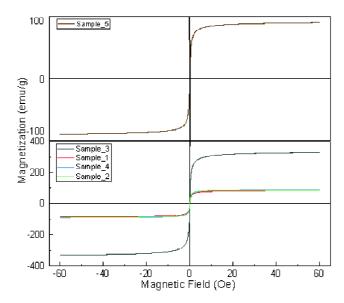

Fig. 6. PPMS spectra of samples.

Looking at these results, it was observed that the $\rm M_s$ results of samples in Table 5 are not overlap with the $\rm d_{XRD}$ (nm) results by calculated Scherrer's equation in Table 5. In literature doping of Zn, reduce the coercivity and also decrease the crystallite size, but increases the saturation magnetization²⁰.

Table 5. Table of PPMS parameter					
Sample No.	$M_{\rm s}$	H _c	$M_{\rm r}$		
Sample_1	83.2	24	1		
Sample_2	85.6	65	9		
Sample_3	331	2	0		
Sample_4	88.3	14	1		
Sample_5	89	0	1		

Conclusions

In this study, Zn_{0.25}Fe_{2.75}O₄ nanoparticles are successfully prepared with an average crystallite size of 25 nm. It is showed a good monodispersity by hydrothermal method changing reaction conditions using NH₄OH as a base. It was approved that the hydrothermal conditions such as reaction temperature and time both had significant effects on structure and magnetic behaviour of nanoparticles. It was observed that the increase in reaction temperature caused increased the nanoparticle size. Besides, increased particle size affected magnetic analysis results, and saturation magnetization value decreasing with increasing particle size. Among

different conditions, Sample_5 nanoparticles synthesized at 180°C for 12 h had good crystallinity and high saturation magnetization of 89 emu/g.
